segment composed of single adults, couples, or elderly individuals. Although they may have fewer dependents, these households still face the rising cost of fresh produce and may lack the physical capacity or knowledge to sustain food-growing initiatives on their own. Only 13.3% (or 2 respondents) have three to five children, and none reported having more than six, showing that large families are less common in the area. However, these small-numbered but high-need households are likely the most vulnerable to food insecurity, as feeding more dependents requires consistent access to affordable and nutritious food.

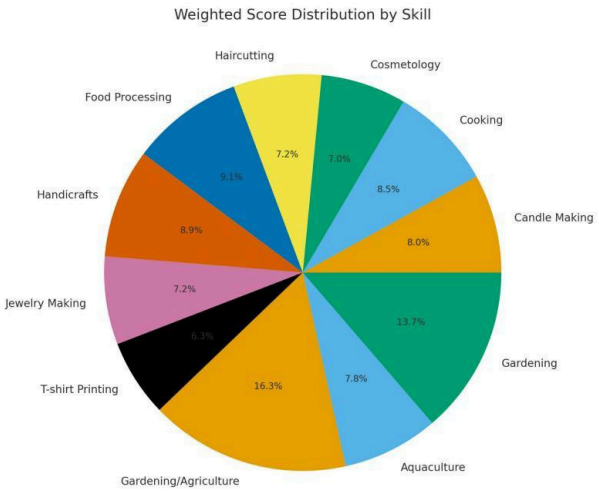

Figure 9: weigh score distribution by skills

The Needs Assessment Survey conducted within the community revealed significant challenges related to food access, rising market prices, and limited availability of fresh vegetables. Many households expressed growing concerns about sustaining their daily food needs, particularly due to financial constraints and dependence on store-bought produce. As a result, the community demonstrated strong interest in acquiring practical skills that support food security, self-sufficiency, and sustainable living. To determine which livelihood and skills training programs are most beneficial, respondents rated various training areas using a five-point priority scale. The analysis incorporated total responses, weighted scores, and top-priority (N5) ratings to clearly identify the most urgent community needs. These results show that both traditional and urban gardening are viewed as the most critical trainings for household survival. Notably, Gardening/Agriculture also received the highest number of N5 (Top Priority) votes, confirming that residents see food cultivation as essential. This aligns

directly with the community’s lived experiences with increasing food costs and limited
